Veloso² and for the ImPrEP Study Group

Abstract

Background: In order to end the HIV epidemic by 2030, combination HIV prevention including pre-exposure prophylaxis (PrEP) should be widely available, especially for the most vulnerable populations. In Latin America and the Caribbean (LAC), only 14 out of 46 countries have access to PrEP. In Brazil and Mexico, PrEP has been provided at no cost through the Public Health System since 2017 and 2021, respectively. Thus, HIV physicians' perspectives about PrEP and other prevention strategies may differ. This study aimed to compare awareness, knowledge, and attitudes related to PrEP and other prevention strategies among HIV physicians from Brazil and Mexico.

Methods: Cross-sectional, web-based survey targeting physicians who prescribe antiretrovirals from both countries. Participants answered questions on socio-demographic, medical experience, awareness, knowledge, and attitudes towards PrEP and other HIV prevention strategies. We stratified all variables per country and compared frequencies using Chi-square, Fisher exact, and Wilcoxon-Mann-Whitney tests, as appropriate.

Results: From January–October 2020, 481 HIV physicians were included: 339(70.5%) from Brazil, 276(57.4%) male, and median age was 43 years (IQR = 36–53). Awareness of PrEP did not differ between Brazil and Mexico (84.6%), while awareness of other prevention strategies, including post-exposure prophylaxis and new PrEP technologies, was higher in Brazil. More Brazilians perceived U=U as completely accurate compared to Mexicans (74.0% vs. 62.0%, $P < .001$). Willingness to prescribe PrEP was 74.2%, higher among Brazilians (78.2%, $P = .01$). Overall, participants had concerns about consistent access to PrEP medication and the risk of antiretroviral resistance in case of acute HIV

Full list of author information is available at the end of the article

infection or seroconversion. The main barriers reported were assumptions that users could have low PrEP knowledge (62.0%) or limited capacity for adherence (59.0%). Compared to Brazilians, Mexicans reported more concerns and barriers to PrEP prescription (all; $P \leq .05$), except for consistent access to PrEP medication and the lack of professionals to prescribe PrEP (both; $P \leq .01$).

Conclusions: Although awareness of PrEP was similar in Brazil and Mexico, differences in knowledge and attitudes may reflect the availability and stage of PrEP implementation in these countries. Strengthening and increasing information on PrEP technologies and other HIV prevention strategies among HIV physicians could improve their comfort to prescribe these strategies and facilitate their scale-up in LAC.

Keywords: Pre-exposure prophylaxis, Post-exposure prophylaxis, HIV, Physicians, U=U slogan, Treatment as prevention, Brazil, Mexico, Latin America

Background

The annual number of new HIV diagnoses has not changed since 2010 (100,000 new infections), with 2.1 million people living with HIV in Latin America and the Caribbean (LAC) by the end of 2020 [1]. Gay, bisexual, men who have sex with men (MSM) and transgender women (TW) remain the most affected populations in the region [1]. In order to end the HIV epidemic by 2030, combination HIV prevention should be widely available especially for the most vulnerable populations, with strategies including behavioral, biomedical, and structural approaches based on human rights, and community-based interventions, such as gender-affirming approaches [2, 3]. Pre-exposure prophylaxis (PrEP) is an effective biomedical prevention strategy to prevent new HIV infections [4, 5]. The World Health Organization strongly recommends the incorporation of daily oral PrEP with tenofovir disoproxil fumarate 300mg and emtricitabine 200mg (TDF/FTC) into combination HIV prevention package since 2016 [6]. Nevertheless, by the end of June 2021 only 14 out of 46 LAC countries had access to PrEP, mostly through private clinics, nongovernmental organizations, pilot studies, or implementation/demonstration projects [7].

Brazil and Mexico host half of LAC population and have the largest gross domestic product in the region [8]. Both countries provide combination HIV prevention at no cost through the public health system, including condoms, post-exposure prophylaxis (PEP), test and treat, and antiretroviral (ARV) treatment for all people newly diagnosed with HIV [9, 10]. However, there is different PrEP availability in the two countries [7, 9, 10]. Brazil participated in the iPrEX clinical trial (2007–2010) [11] and conducted the PrEP Brasil Demonstration Study to evaluate acceptability, retention, and adherence of PrEP among MSM and TW (2014–2016) [12]. These two experiences paved the way for Brazil to start providing PrEP at no cost through its national public health service (Brazilian Unified Health System – *SUS*, in Portuguese) since 2017 [13]. By October 2021, 47,821 Brazilians had

initiated PrEP and 27,236 were using PrEP [14]. The Implementation PrEP project (ImPrEP) aims to generate evidence on the acceptability, feasibility, and cost-effectiveness of PrEP among MSM and TW in Brazil, Mexico and Peru, including a large PrEP demonstration study conducted from 2018 to 2021 [15]. ImPrEP was the first opportunity for Mexico to provide PrEP in three cities (Mexico City, Guadalajara and Puerto Vallarta), with 2445 participants under follow-up by the end of June 2021 [16]. In 2021, the Mexican National HIV Program (CENSIDA, in Spanish) and the social security health system launched national pilot PrEP programs [17, 18]. PrEP availability and demand creation including awareness and knowledge of users and health care professional are fundamental for PrEP scale-up among populations vulnerable to HIV. Until 2020, only HIV physicians in the public sector could prescribe PrEP in these two countries. The different stages of PrEP availability and implementation in Brazil and Mexico could lead to differences in HIV physicians' perspectives about PrEP and other prevention strategies.

Awareness and willingness to prescribe PrEP may increase depending on PrEP availability in the health systems [19]. Nevertheless, physicians may have concerns or perceived barriers about prescribing PrEP [20]. Low knowledge about PrEP, lack of time, cost, antiretroviral resistance, the *purview paradox* (the belief that PrEP prescription is beyond one's clinical domain), interpersonal stigma, anticipated risk compensation, and PrEP adherence were the main reported concerns of health care physicians in the USA [20–23]. Low willingness to prescribe PrEP has been associated with providers' racial bias or prejudice about key populations behavior, especially in their PrEP adherence capacity [24, 25]. Studies in LAC reveal variations in awareness and willingness to prescribe PrEP among general practitioners or physicians with a medical specialty. In 2015, in Guatemala, 69% of internal medicine and infectious disease trainees reported awareness of PrEP, and 87% had willingness to prescribe it [26]. In Brazil, a study conducted between

2016 and 2017 showed that 75% of infectious disease physicians were aware of PrEP, and between 63 and 69% reported willingness to prescribe PrEP for MSM or sex workers with inconsistent condom use [27]. However, such information is not available for Mexico and for Brazil after PrEP implementation in December 2017.

As part of the ImPrEP project, we conducted a web-based survey among HIV physicians from Brazil and Mexico to understand awareness, knowledge, experience, and attitudes related to PrEP and other HIV prevention strategies, as well as to compare both countries considering the differences in PrEP implementation stage.

Methods

Study design

This was a cross-sectional web-based survey targeting HIV physicians who prescribe ARV from Brazil and Mexico. In both countries, most ARV prescriptions, including PrEP, are performed by physicians working in the public health system (either general practitioners or infectious diseases specialists). HIV physicians who signed electronic informed consent were included. We excluded participants who previously participated in the survey. We used Alchemer® (Brazil) and SurveyMonkey® (Mexico) for programming the questionnaire. The survey was designed based on previous studies [21, 23, 26, 27], and consisted of 37 questions in 22 pages. Participants could only answer questions on one page after completing all items on the previous page. The items related to perceived barriers, concerns or attitudes had a 4-point Likert scale to avoid intermediate options and reduce social desirability bias [28]. We piloted the questionnaire to a small sample of physicians with experience in ARV prescription in both countries. The research team discussed the post-pilot suggestions and adjusted items as needed.

In Brazil, the survey was conducted between January 28 and October 20, 2020. The questionnaire link was sent by e-mail using Mailchimp® to all HIV physicians registered at *Siclom* (Brazilian National System for antiretroviral prescription and dispensation) and at the Federal Medicine Council (CFM). Those who did not initially respond were sent up to two additional emails. In Mexico, we sent weekly e-mails to HIV physicians between March 15 and September 4, 2020. Twenty-seven out of 32 State HIV Representatives from Mexico provided a list containing 267 HIV physician e-mail contacts.

Variables

Socio-demographic and medical experience

We collected the following demographic characteristics: age (stratified in 26 to 34, 35 to 49, ≥ 50 years; and provided as median and interquartile range [IQR]), gender

(male/female), race/skin color (White, Mixed [*Mestizo* in Mexico and *Pardo* in Brazil], Asian, Black and Indigenous), region of residence (Brazil: North, Northeast, Central-west, Southeast, and South; Mexico: Northeast, North Centre, South Centre, South, West, and East) and living in metropolitan area of State capitals (yes/no). Participants were asked about their medical experience: infectious diseases specialist (yes/no), number of years as medical doctor (MD; ≤ 5 , 6–10, 11–15, 16–20, and > 20 years), and number of patients living with HIV under follow-up (None, 1–19, 20–49, ≥ 50).

Awareness of combination HIV prevention strategies including new PrEP technologies, and comfortableness on prevention counseling

We assessed awareness of combination HIV prevention and PrEP with two separate questions: “Have you ever heard of the combination HIV prevention concept (or PrEP)?”, using a 4-Likert scale for response options (*Not at all* to *Very much*). For the analysis, we considered participants who responded *Much* or *Very much* as aware. We provided a pre-existing list of other prevention strategies (ie, condoms, treatment as prevention, serosorting, etc) including new PrEP technologies, such as event-driven PrEP and cabotegravir injection [29, 30], and asked HIV physicians to choose all strategies they had previously heard about.

Participants were asked if they would feel comfortable performing activities related to HIV and sexual transmitted infections (STI) prevention (ie, discussing sexual behavior, requesting STI exams, etc). We presented possible answers in a 4-Likert scale (*Completely uncomfortable* to *Completely comfortable*) and participants were considered comfortable to perform such activities if they answered *Completely comfortable* or *Comfortable*. Participants were also asked about their awareness of the different PrEP technologies, such as TDF/FTC daily dose and cabotegravir injection (yes/no) [29, 30].

Knowledge and attitudes regarding PrEP, PEP and U=U slogan

HIV physicians answered whether they had knowledge of PrEP and PEP national guidelines or had ever received any training, prescribed, or referred a client to receive PrEP or PEP (yes/no). We also asked participants their willingness to prescribe PrEP and in which context or setting they had previously prescribed it: private office, demonstration studies, clinical trials and/or SUS (only for Brazilian participants) (all yes/no). For PEP, we asked about reasons for PEP prescription (occupational, sexual violence, and consensual sex; multiple options were available). Perceived accuracy of the undetectable equals untransmittable (U=U) slogan was assessed following

previous studies (completely accurate vs. not) [31, 32]. Participants were also asked if they had ever been trained on the U=U (yes/no).

Populations who would benefit from PrEP, healthcare services that should offer PrEP, and reasons for not offering PrEP

We asked HIV physicians which populations would benefit from PrEP from a pre-existing list and which healthcare services should offer PrEP (HIV/STI clinics, specialized clinics, family clinics, private clinics/hospitals and primary care); possible answers were *yes/no* and multiple answers were permitted. We also asked about reasons PrEP should not be offered: “Public PrEP will reduce the budget for antiretroviral treatment”; “Behavioral interventions should be prioritized instead of PrEP”; “Low demand of PrEP users to maintain PrEP as public policy”; “I think PrEP should not be provided by public services”. For each of these items, responses were gathered using a 4-Likert scale (*Strongly disagree to Strongly agree*), *Strongly agree* and *Agree* responses were considered as *yes*.

Perceived concerns and barriers to prescribing PrEP

We provided a pre-existing list of concerns about prescribing PrEP (for instance, consistent access to PrEP medication and risky behavior increase) with possible answers in a 4-Likert scale (*Not concerned to Extremely concerned*); responses *Somewhat/Extremely concerned* were considered as *yes* for analysis. We also provided a pre-existing list of barriers to prescribe PrEP, with possible answers in a 4-Likert scale (*Not a barrier to Strong barrier*); responses *Moderate/Strong barrier* were considered as *yes*.

Ethics and consent to participate

This study was approved by the Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz) Institutional Review Board (CAAE: 94050418.4.0000.5262) in Brazil and the Research Ethics Committee of the National Institute of Psychiatry Ramón de la Fuente Muñiz (CEI/C/038/2018) in Mexico. We did not collect participants' identification or provide any incentives.

Statistical analysis

We used only completed surveys for analysis and we described all study variables frequencies in total and for each country (total number of responses and percentages considering sample size). We compared responses between HIV physicians from Brazil and Mexico using Chi-square and Fisher exact test for categorical variables and Wilcoxon-Mann-Whitney for the continuous variable (age), as appropriate. Questions contained

response options *I do not want to answer*, and *I do not know*, which were considered as missing data for analysis and not included in the frequency calculation. The items related to perceived barriers, concerns or attitudes scales were presented in absolute numbers and frequencies; scales were not developed to provide scores. Differences between countries were considered using a threshold $P \leq .05$ for statistical significance. All analyses were performed using Stata/IC 15. Datasets generated and analyzed in this study are available (Additional file 1).

Results

Of 704 participants who accessed the survey, 674 (95.7%) acknowledged informed consent and 541 (76.8%) completed the survey. Of these, 11.1% (60/541) reported previous participation in the study and were excluded. Our final sample was composed of 481 HIV physicians, 339 (70.5%) from Brazil and 142 (29.5%) from Mexico. Median age was 43 (IQR 36–53) years; most were male (279/481, 57.4%), self-identified as White (303/481, 63.9%), lived in metropolitan areas of state capitals (327/481, 68%), and were infectious disease specialists (333/481, 69.4%). Compared to Mexico, more HIV physicians from Brazil were younger (26–34 years; 22.3% vs. 12%; $P = .01$), White race (81.2% vs 22.3%; $P < .001$), infectious disease specialists (79.1% vs 46.1%; $P < .001$) and more experienced as MD (> 20 years; 44.2% vs 36.6%; $P = .05$). Conversely, Mexican physicians had more patients living with HIV under follow-up (≥ 50 patients; 91.3% vs 50.9%; $P < .001$) (Table 1). Most of the Brazilian HIV physicians reported living in the Southeast (55.4%), followed by South (19.2%), Northeast (13.9%), Central West (7.4%), and North (4.1%). For Mexico, most were from the South region (43.7%) followed by Northwest (23.2%), East (11.3%), West (9.2%), Northeast (6.3%), North Centre (5%), and South Centre (1.4%).

Overall, awareness of PrEP and other prevention strategies varied from 48.4% to 87.1% for cervical exams and PEP, respectively (Table 2). Awareness of PrEP was 84.6%, with no difference between countries ($P = .25$). Nevertheless, Brazilian HIV physicians were more aware of most prevention strategies including new PrEP technologies than their Mexican counterparts ($P \leq .05$), except for daily oral TDF/FTC or tenofovir alafenamide/emtricitabine (TAF/FTC) ($P \geq .63$). Most HIV physicians reported being comfortable performing all HIV/STI prevention activities evaluated with no difference between countries ($P \geq .20$), except risk-reduction counseling, which was higher among Mexican compared to Brazilian physicians (99.3% vs 93.5%; $P < .01$).

Most HIV physicians from both countries knew about the national PrEP guidelines, with no differences between countries ($P = .12$) (Table 3). A higher proportion of

Brazilian compared to Mexican physicians were willing to prescribe PrEP (78.2% vs 64.8%; $P < .01$), previously referred a patient to receive PrEP (72% vs 20.6%; $P < .001$) and had previous experience on prescribing PrEP (49.1% vs 33.3%; $P < .01$), while more Mexicans reported prescriptions at private offices (66% vs 45.1%; $P = .01$). Figure 1 provides the PrEP cascade experience (from awareness to prescription) differences between HIV physicians from Brazil and Mexico. More Brazilians than Mexicans knew about the national PEP guidelines (95.9% vs 83.1%; $P < .001$), previously referred a client to receive

PEP (87.3% vs 44.4%; $P < .001$) and reported previous experience on prescribing PEP (92.6% vs 69.7%; $P < .001$), including all reasons for prescribing PEP. In Brazil, more HIV physicians perceived the U=U slogan completely accurate than in Mexico (74.0% vs 62%; $P < .001$), while more Mexicans had been previously trained in U=U (62% vs 38.6%; $P < .001$).

HIV physicians from both countries reported that MSM, sex workers, transgender people, and partners in sero-discordant relationships would be the populations benefiting the most by PrEP (Table 4). Conversely, more

reported for not offering PrEP in both countries was the prioritization of behavioral interventions instead of PrEP (54.3%, overall).

Perceived barriers and concerns to prescribe PrEP varied across countries (Table 5). Overall, more Mexican HIV physicians reported concerns and barriers to prescribe PrEP than Brazilians (for all, $P \leq .05$), but more Brazilians reported concerns related to consistent access to PrEP medication (82.9% vs 68.3%; $P < .001$) and barriers related to lack of professionals to prescribe PrEP (62% vs 46.5%; $P < .01$).

Discussion

Our results describe awareness, knowledge, and attitudes related to PrEP and other prevention strategies among HIV physicians from Brazil and Mexico and compare the differences between countries. Although awareness was similar in both countries, willingness to prescribe PrEP was higher in Brazil than Mexico, while barriers and concerns were more frequent in Mexico, which may be

explained by the different stages of PrEP implementation in both countries. Awareness and willingness to prescribe PrEP (84.6% & 74.2%) were higher than previous studies conducted in LAC in Guatemala City (69% & 87%) and São Paulo, Brazil (75% & 63–69%) [26, 27], possibly due to increased information about PrEP over time and PrEP implementation in the Brazilian SUS since December 2017 [13]. Our results offer updated information to inform the Ministry of Health, stakeholders, clinicians and policy makers from Brazil, Mexico and other LAC countries on different stages of PrEP implementation [33].

Awareness of all other HIV prevention strategies except daily oral PrEP, including new PrEP technologies, was higher in Brazil than in Mexico [29]. A broader dissemination of information on combination HIV prevention including all available strategies is needed among Mexican HIV physicians to increase their knowledge beyond condoms, PEP, or PrEP. Increasing awareness and knowledge of new PrEP

technologies under development or recently approved by regulatory agencies, such as cabotegravir injection [30] among healthcare workers in addition to HIV physicians could impact the acceptability and willingness to prescribe these technologies when they become available. Furthermore, almost all HIV physicians reported feeling very comfortable providing HIV/STI prevention counseling and performing clinical activities required for PrEP screening in clinical facilities [21] reflecting a positive attitude towards PrEP.

Although both countries established PEP policies more than 10 years ago [34], previous experience with this prevention strategy was more frequent among Brazilians. Over three-quarters of Brazilian HIV physicians previously prescribed PEP for all evaluated reasons for PEP use (occupational, consensual sex and sexual violence). Conversely, almost half of Mexicans prescribed PEP for occupational and sexual violence and only 26% for consensual sex. These results are worrisome and may indicate stigma and judgement by HIV physicians concerning sexual behavior. Continuous refreshing training and campaigns among Mexican HIV physicians should focus on recommending that PEP should be offered to all individuals with PEP criteria regardless of the reason of HIV exposure, and address physicians' beliefs.

The proportion of Mexican HIV physicians trained in U=U was higher compared to Brazilians, although a lower proportion of Mexicans perceived the U=U slogan to be accurate. Still, proportions of HIV physicians perceiving U=U as accurate in both countries were still low considering the available scientific evidence of treatment as prevention [35–37] and efforts to increase U=U slogan more broadly since 2018 [38]. Reasons for health providers including HIV physicians to not fully embrace the U=U concept were persistent lack of trust and confidence, and a tendency to withhold the U=U slogan during counseling or clinical visits [39]. Either disbelief, concerns about risk compensation, or stigma towards stereotyped sexual behavior among people living with HIV usually result in a conservative message regarding U=U [40, 41]. Wider dissemination of the protective and preventive power of the U=U slogan among HIV physicians could improve their confidence in conveying this message to their patients living with HIV and help reduce the HIV-related stigma [31].

Brazilian and Mexican HIV physicians agreed that MSM would benefit from PrEP, possibly related to the high rates of HIV prevalence among this population [42]. However, it is worrisome that a relative low proportion of Mexicans did not consider that PrEP would benefit sex

workers, transgender people, partners in sero-discordant relationships, and substance users, all populations at increased vulnerability for HIV infection in Mexico [43]. This could be a reflection of HIV physicians' beliefs that these populations would not have the ability to adhere to daily oral PrEP and be retained at the clinic for follow-up visits [21]. For example, HIV physicians may delay ART initiation among substance users with recent HIV diagnosis due to their perception of substance users' diminished ability to adhere to the treatment [44–46]. The same rationale could be used by HIV physicians prescribing PrEP to such populations. However, in a recent study conducted in Brazil, transgender women showed high rates of retention after 1 year of PrEP provision and this was attributed to the gender-affirming setting [3]. Welcoming services to the most vulnerable populations may not only increase their retention but also HIV physicians' perception on who can benefit from PrEP. Lastly, lower proportion of Brazilians considering that PrEP should be beneficial for any population may be related to high awareness of PrEP recommendations in Brazil, as PrEP is cost-effective only when offered to populations with HIV incidence higher than or equal to 3% [6].

Less than half of all the HIV physicians in both countries indicated that primary care and family clinics should offer PrEP, in contrast to some studies showing that HIV physicians believe that primary or family care physicians should prescribe PrEP because they have more HIV-uninfected patients (*purview paradox*) [23]. In our sample, the majority felt that specialized or HIV/STI clinics would be the most appropriate setting to offer PrEP, probably due to the belief that the physicians in these clinics have more experience prescribing ARV. It is striking that a large proportion of Mexicans agreed that behavioral interventions should be prioritized instead of PrEP use. Increasing the information on the efficacy of behavioral interventions in reducing HIV risk among vulnerable populations compared to the efficacy of PrEP could address this perception bias [47]. Concerns about budget reductions for ART if PrEP were available has been reported in both high- and low-income settings [20, 26].

Perceived barriers and concerns found in our study were similar to those reported by other studies in countries with PrEP availability [21, 22, 26, 27]. In general, ARV resistance or increased sexual risk behavior are common concerns among physicians who can prescribe PrEP to vulnerable populations [21]. However, barriers and concerns were more frequent among Mexicans in 13 of 15 items evaluated here, especially those related to PrEP medication and its daily use. Only those related to the public health system (consistent provision of PrEP and lack of professionals to prescribe PrEP) were higher

among Brazilian HIV physicians, reflecting the concerns of physicians in countries where PrEP is already a public health policy. The recent decision to extend PrEP prescriptions to nurses in Brazil may reduce the concern related to available personnel for prescriptions [48].

Strengths & limitations

As strengths, our study is the first to assess the awareness, knowledge, experience, and attitudes related to PrEP and other prevention strategies among HIV physicians from Brazil and Mexico, after these countries approved PrEP as a public health policy or conducted an implementation project. In addition, our results show that the perceived barriers or concerns to prescribing PrEP among physicians are different according to the stage of implementation, so there is a need to address these differences. Conversely, our study has some limitations. The cross-sectional design cannot identify associations or causality between the perceived barriers or concerns and the willingness to prescribe PrEP. We did not assess physicians' sexual orientation which might have influenced their willingness to prescribe PrEP for key populations, such as MSM or TW. Also, this was a convenience sample, and our results cannot be generalized to all physicians from both countries, including the self-reported collection of data that could be subject to social desirability bias. We had a loss of 32% of participants who accessed and did not complete the survey, which could represent a lack of interest in PrEP or other prevention HIV strategies.

Conclusions

In countries where the HIV epidemic is concentrated among historically stigmatized populations, such as LAC, combination HIV prevention strategies offer an opportunity to reduce new HIV infections. In addition to promoting PrEP use and other HIV prevention strategies among populations vulnerable to HIV, training, awareness-raising, and promotion of prescribing among physicians should also be strengthened. Depending on the stage of PrEP implementation, physicians may perceive obstacles related to the provision of services or lack of information to prescribe PrEP. These barriers should be addressed by HIV national programs in LAC to increase the number of people using HIV prevention technologies, contributing to the goal of ending the HIV epidemic by 2030.

Additional file 1. Dataset PrEP Survey with Physicians from Brazil and Mexico 2020. This file contains the raw data from a survey performed in 2020 about the awareness, knowledge, and attitudes related to pre-exposure prophylaxis and other prevention strategies among physicians from Brazil and Mexico.

Acknowledgments

We thank the Brazilian Ministry of Health staff Antonio Ramos de Carvalho, and the Mexican National (CENSIDA) & States' HIV Programs, and all physicians who answered the study survey. We also thank Lorena Hernández-Cariño for help on data collection, and Alicia Piñeirúa-Menéndez who facilitated the contact with each States' HIV Program coordinators. Special thanks to the UN Population Fund office in Mexico for their support in this project.

Authors' contributions

HV-R and TST did the literature search. HV-R, TST and KAK conceived the questionnaire. HV-R, TST, KAK, DD-S, DRBB and CG-D worked on the advertisement of the questionnaire. HV-R and TST performed data cleaning. HV-R and TST analyzed the data and generated the tables and figures. HV-R, TST and KAK reviewed the statistical analyses. HV-R and TST interpreted the data and drafted the manuscript. KAK, DD-S, CG-D, RR-G, BH, CP, MB, BG, CFC and VGV substantially revised the manuscript for important intellectual content. All authors read and approved the final manuscript.

Funding

This project was made possible thanks to Unitaids' funding and support. Unitaids accelerates access to innovative health products and lays the foundations for their scale-up by countries and partners. Unitaids is a hosted partnership of WHO. We would like to thank the support of the MoHs of Brazil and Mexico. Thiago S. Torres acknowledge funding from Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) and Fundação de Amparo a Pesquisa do Estado do Rio de Janeiro (FAPERJ).

Availability of data and materials

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Declarations

Ethics approval and consent to participate

The Institutional Review Board of the Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz) approved the study for Brazil (CAAE: 94050418.4.0000.5262); and the Research Ethics Committee of the National Institute of Psychiatry Ramón de la Fuente Muñiz approved it for Mexico (CEI/C/038/2018). All methods were performed in accordance with the guidelines and regulations of each country, and all participants accepted the informed consent before starting the survey.

Consent for publication

Not applicable.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
